This invention relates to a multi-layer battery and to a process for producing it. More particularly, the invention relates to a multi-layer battery in which the positive electrode and negative electrode are constituted by a mixture of a lithium metal and an inorganic substance such as graphite, the above-mentioned positive electrode being fabricated by pressing this mixture in layers, and to a process for producing this multi-layer battery. The above multi-layer battery is already known from the specification of U.S. Pat. No. 4,957,751 (corresponding to Japanese Patent Application No. Sho 61-2013085) in which lithium is used for the negative electrode and a material such as carbon capable of absorbing and desorbing lithium ions is used for the positive electrode. The battery is constituted by a plurality of stacked electrode cells each of which has positive and negative electrodes composed of an active material capable of absorbing and desorbing lithium ions and current collectors, the electrode layers being interposed with separators. Further, by using lithium as the negative electrode, a higher energy density than that of alkali batteries can be obtained, and the battery has a relatively stable cycle characteristic in contrast to organic electrolytic solution secondary batteries. Thus, the positive electrode can be constructed by using an active material that absorbs and desorbs lithium ions, and a battery having a high energy density and a high current collecting efficiency can be realized. However, in the above-mentioned conventional multi-layer battery, the active f678ea9f9e
